# **Atoms and Molecules**

#### Atoms

## According to Dalton's atomic theory

- Matter is made up of very tiny particles and these particles are called atoms.
- Atoms cannot be divided further i.e., atoms are indivisible
- An atom can be defined as the smallest particle of matter that can neither be created nor destroyed by chemical means.

### • Laws of Chemical Combination

- Law of conservation of mass
- o Mass can neither be created nor destroyed in a chemical reaction. It means that the sum of the masses of the reactants and the products remains the same during a reaction.

### Laws of Chemical Combination

## • Law of constant proportion

- A chemical substance always contains the same elements in a fixed proportion by mass, irrespective of the source of compound.
- The size of an atom is indicated by the radius of the atom called the **atomic radius**. It is often expressed in **nanometers**.

### Representation of atoms

- The symbol of the element is made from one or two letters of the English or the Latin name of the element.
- Symbols are significant as they represent a particular element and they represent one atom of that element.

### Atomic Mass

- The mass of an atom is known as the atomic mass.
- The atomic mass of an atom of an element is also known as its relative atomic mass, since it is determined relative to the mass of C-12 isotope.
- **Gram molecular mass:** The mass of one mole of atoms is known as the **molar mass of atoms**, **gram atomic mass**, or **gram atoms**. For example, the atomic mass of nitrogen is 14 u and the gram atomic mass of nitrogen is 14 g. The mass of one mole molecules of any

substance is equal to the **gram molecular mass** of that substance.

- **Relative atomic mass or atomic weight:** It is the ratio of mass of one atom of an element to the mass of an atom of hydrogen taken as unity.
- **Gram molecular volume:** The volume occupied by 1 gram molecule of a dry gas at S.T.P is called gram molecular volume. The experimental value of 1 gram molecular volume of a gas is 22.4 L at S.T.P.

#### Molecule

- A molecule is formed when two or more atoms of the same element or different elements get combined chemically.
- o The number of atoms that combine to form a molecule is called the atomicity of the molecule

#### Ion

- An ion is a charged species in which an atom or a group of atoms possess a net electric charge (positive or negative).
- o Positively charged ions are called cations (basic radical) and negatively charged ions (acidic radical) are called anions.
- Compounds in which molecules are formed by the combination of cations (positively charged ions) and anions (negatively charged ions) are known as ionic compounds.

#### Chemical formula

- A chemical formula is the representation of the composition of a molecule in terms of the symbols of elements present in that molecule.
- Molecular formula is a chemical formula that indicates the kinds of atoms and the numbers of each kind of atom in a molecule of a compound.
- To write the chemical formula of a compound, one should have prior knowledge of two things.
- The symbols of the constituent elements.
- o The combining capacity of the atom of each element constituting the compound.

### Molecular Mass

o The molecular mass of a substance is the sum of the atomic masses of all the atoms present in a molecule of that substance.

#### Formula unit mass

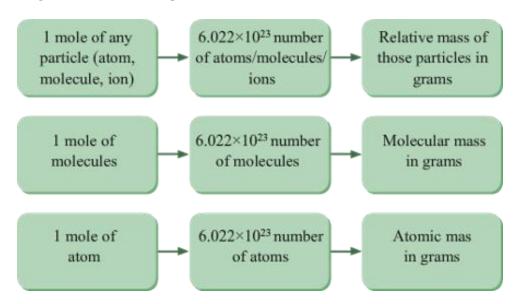

• The formula unit mass of a substance is the sum of the atomic masses of all the atoms present in a formula unit of that substance.

## • Mole Concept

- One mole of a substance is the quantity of the substance containing  $6.022 \times 10^{23}$  numbers of particles (atoms, molecules, or ions). The number i.e.,  $6.022 \times 10^{23}$  is known as the Avogadro number. It means that one mole of any substance (element or compound) contains  $6.022 \times 10^{23}$  particles (atoms of molecules).
- o The mass of 1 mole of a substance is known as its molar mass.

$$Molar mass = \frac{Mass of substance}{Number of moles}$$

• Avogadro's Law: Under the same conditions of temperature and pressure, equal volumes of all gases contain the equal number of moles.

• Gay-Lussac's Law: At constant volume, the pressure of a fixed amount of a gas is directly proportional to the temperature.

$$\frac{p_1}{T_1} = \frac{p_2}{T_2}$$
