Water

Sources of Water

Do you know that on an average an individual consumes about 2.9 litres of water everyday?

Water is required not only for drinking but also for many other purposes in our day-to-day lives.

Irrigation in agriculture, industrial processes, domestic purposes such as cooking and cleaning are some of the major uses of water.

What are the sources of water?

We know that water is available from various sources. Some of the common sources of water are ponds, lakes, rivers, wells, and reservoirs.

The water that we use in our homes is supplied from these sources. In villages, people directly use water from the ponds, rivers, lakes, canals, reservoirs etc.

Is water in icebergs salty?

The water in icebergs is not salty, rather it is fresh water. This can be explained by the principle of freezing. Iceberg is the solidified form of water. During the process of solidification the water molecules come close to one another and get packed tightly. This leaves no space for the molecules of salt.

Where does the water in these ponds, lakes, rivers, and wells come from?

Recall a picture of the globe. The area covered by the land is very small as compared to the area covered by water. Water covers two-third (2/3) of the total surface area of the world.

Interestingly, did you know that some of the water from the oceans and seas evaporates and is the primary source of rain? Rainwater feeds into the ponds, lakes, rivers, and wells etc, which in turn are the main sources of water for us.

You may be familiar with instances of the taps in your house running dry for days at a stretch, on account of a shortage of water in your city. We know that there are places in this country where the shortage of water is so severe that people

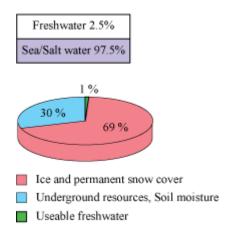

stand in long queues to fetch a few buckets of water! In the villages people have to fetch water from very far distances.

There are numerous fights over water. Marches and protests, against the unavailability of this valuable resource, are fairly common. All these problems are due to the limited availability of fresh water as a resource.

Interestingly, did you know that another name for our planet is 'Blue planet'? This is because our planet appears to be blue in color when seen from the outer space. This color is because a vast area on Earth is covered with water.

You may know that about 71% of the total surface area of the Earth is covered with water that is contained in the oceans, seas, lakes, rivers, ponds, etc. The remaining 29% is the land surface area. If such a large area is covered with water, then **why is there a scarcity of water?**

Water on the Earth is found in the oceans, seas, lakes, ice caps, rivers, ponds, under the ground, and also in the atmosphere as vapor. The oceans and seas alone account for about 97.5 % of the total water found on the surface of the Earth. This water from the oceans and seas is not suitable for human consumption as it is salty. The remaining 2.5 % is fresh water and is found trapped in the ice caps, glaciers, ponds, lakes, rivers and underground water that is suitable for use.

Source of fresh water	Percentage
Ice and glaciers	69%
Ground water	30%
Surface water	1%

We basically use both surface water and ground water. We obtain ground water by using wells and tube wells.

This is the reason why we face scarcity of water.

Let us perform an activity to understand the amounts of water available in different forms

Collect the items listed below

- A test tube
- A ladle or dropper of 5 ml capacity
- A beaker of 500 ml or larger capacity
- A bucket with a capacity of more than 20 litres
- A small beaker of 150 ml capacity

1.Pour 20 litres of water in a bucket.

These twenty litres of water represents the total water available on Earth.

2.When 100 ladles of water from this bucket is removed it amounts to 500 ml of water. (100 ladles of 5 ml capacity each)

This 500 ml of water in the beaker represents the fresh water available on the Earth.

3.When 30 ladles of water from this beaker is transferred to another beaker, it amounts to 150 ml of water. (30 ladles of 5 ml capacity each)

This 150 ml or 30 ladles full of water represents the usable ground water.

4.When a quarter or $\frac{1}{4}$ th of this 150 ml of water is removed into another beaker, it amounts to 37.5 ml or 7.5 ladles of water. (A quarter of 150 ml means $\frac{150}{4} = 37.5$ ml of water, i.e. 7.5 ladles of water)

This 37.5 ml or 7.5 ladles represents the water in all lakes, rivers, ponds etc of the world.

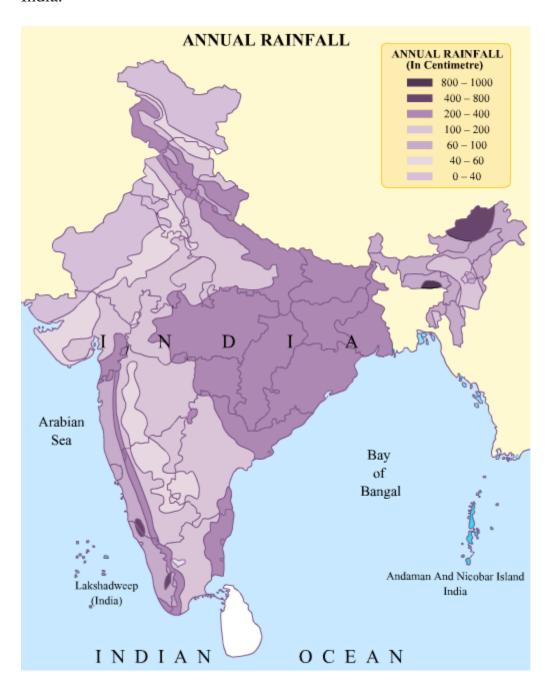

Thus, the quantity of usable water that is available on the Earth's surface is very small in comparison to the total available water on Earth. Therefore, water is indeed a limited resource and should be conserved.

Distribution of Water in India

In India, water availability is greatly dependent on the seasonal monsoons. The distribution of rain water varies in different parts of the country. Some regions such as the north eastern states and the Western Ghats receive excess rainfall while regions of western India such as the Thar desert of Rajasthan do not receive adequate rainfall.

This uneven distribution of rain causes floods in some areas and droughts in the parts where there is scanty rainfall.

The given map shows the average annual rainfall received by the different parts of India.

Need for Water Conservation

We use water for several purposes

• Domestic purposes such as drinking, washing, cooking, gardening etc.

- Personal hygiene such as brushing, shaving, bathing etc.
- Recreation or water sports, fountains, decorations, etc.

Can you recall more and add to the list?

Water is very important as it is utilized in many activities. Water is not only required by human beings for their various needs but is also required by plants and animals for their survival and growth.

Let us understand more. John and Stalin plant two rose plants in their homes. John waters his plant everyday but Stalin does not. After a few days, Stalin's rose plant sheds its leaves and dries up while John's rose plant is healthy and has flowers.

Do you know why Stalin's plant looses its leaves? This is because water is essential for the growth of plants.

We know that water is essential for many activities in our homes.

Consider a family of four comprising two adults (the parents) and two children (Amit and Amrita). Let us try and list their normal activities and the amount of water utilized respectively.

Family members	Activities	Approximate water utilized(in buckets)
Father	Personal hygiene	2

	Car wash	1
Mother	Personal hygiene	2
	Cooking	1
	Cleaning	2
Amit	Personal hygiene	2
Amrita	Personal hygiene	2
		Total:12

(Note: Although water is also utilized for many other purposes, for the sake of convenience only a few activities have been taken into account.)

Thus, we see that a family of four members utilizes approximately 12 buckets of water for its everyday activities, on a normal day.

If about 20 families live in an area, then the amount of water utilized would increase to $20 \times 12 = 240$ buckets per day (considering four to be the average number of members per family).

Can you now imagine how much water is required by all the people living in the world?

Do you know how much usable water is available on the Earth?

Ocean and seawater contribute about 97.5% of the total water available on the Earth and the remaining 2.5% is fresh water.

You will be surprised to know that out of this 2.5% fresh water, 69% of it is frozen in the form of ice-caps in the Polar Regions. About 30% percent of it is found as underground water and only the remaining 1% is available as water in the lakes, ponds, and rivers!

With the increase in population, there is an increase in the agricultural and industrial activities, recreation etc which has further led to an increase in the amount of water utilized by humans.

Water resources are limited and it is decreasing everyday. Therefore, it is very important for all of us to understand that water is precious and needs to be conserved.

Management of water resources in order to increase the efficiency with which it is utilized and decrease the wastage is known as conservation.

A few steps that can help in the conservation of water are

- Careful utilization of water by preventing the spilling, over use and wastage of water. Keeping the taps running while we are washing or brushing leads to a lot wastage of water and should be avoided.
- Rainwater harvesting, that involves collecting and storing the rain water for further use, should be practiced.

Water Cycle

Physical States of Water

Water is found in solid, liquid, and gaseous states in the environment. In the solid state, it is found in the form of ice, and as a liquid, it exists as water. It is present as water vapour in the gaseous state.

Physical Properties of Water

• Water is a colourless, tasteless, and transparent liquid. It also has no smell.

- Boiling point of pure water is 100°C at 760 mm of Hg pressure. However, boiling point of water increases due to increase in pressure and presence of dissolved impurities.
- Pure water freezes at 0°C at 760 mm of Hg pressure. However, freezing point of water decreases due to increase in pressure and presence of dissolved impurities.
- The state of water changes on heating or cooling. On heating, the state of water changes from liquid state to gaseous state (vapour). Similarly, on cooling, the state of water changes from liquid state to solid state (ice).
- Pure water is a bad conductor of heat and electricity.
- Water absorbs a fixed amount of heat. It has been found that 1 g of water always absorbs 4.2 J (=1 Calorie) of heat energy when heated through 1°C. This fixed amount of heat energy is called specific heat capacity. Specific heat capacity is the fixed amount of heat energy required to raise the temperature of 1 g of water by 1°C.

Water undergoes different processes in the environment and is found in different states during these processes. This cyclic process through which water circulates in the environment is called the **water cycle**.

Let us first describe the process of water cycle for you.

By now, you know the steps involved in a water cycle. Now, let us look at each step.

Evaporation

Have you observed that when the floor is wiped with water, the water dries up in some time? The roads and buildings that become wet after rainfall, dry up soon after. You may have also observed that the water level in a container reduces when it is kept in it for a long time.

Where is all this water disappearing?

The process whereby water disappears into air is called **evaporation**. During evaporation, liquid water is converted into gaseous water vapour.

How does evaporation occur? What are the factors that affect evaporation? Let us understand.

Wet two handkerchiefs and squeeze out the water. Dry one of it outside in the sun and the other inside a room. Observe the time taken for both of them to dry. Do they take the same amount of time?

The handkerchief that was put out to dry in the sun dries up faster than the one inside the room. This is because the heat from the sun speeds up the time taken for evaporation. Thus, *heat is essential for evaporation*.

Then how did the handkerchief inside the room dry?

This is because the heat from the sun also heated the air inside the room, although indirectly. This warm air converted the water on the handkerchief into vapor. Since direct sunlight did not reach the room, the handkerchief took longer to dry.

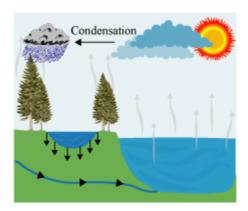

When water is poured over plants kept in pots, it is absorbed by the plant roots. Water is essential for plant growth. The plant utilizes the required quantities of water and the excess water is lost by the surface of the leaves as vapor through the process of *transpiration*.

Thus, we can say that evaporation and transpiration are the processes by which water is converted into water vapor.

Since sunlight falls on all the water bodies such as oceans, seas, lakes, ponds, and rivers, water is being continuously converted to water vapor. Where does all this water vapor go? Does it disappear forever?

Condensation

As water vapor moves higher up, it cools down and forms water droplets through the process of **condensation**. Many water droplets join together to form clouds.

Precipitation

The water vapour that condenses as clouds falls down as rainfall, snow, or hail by the process of precipitation.

When clouds are large and laden with water, the water begins to fall as rainfall.

This rain enters the rivers, ponds, lakes, and other water bodies.

Some of the rainwater that falls on the ground enters the soil and adds to the **groundwater.** The returning of rain water into large water bodies and groundwater is known as **run off**.

This groundwater can be a source of water for the lakes. It can be drawn out using hand pumps and tube wells and utilized. The overuse of groundwater, however, can reduce its availability, thereby increasing water scarcity. When the land surface is covered with concrete, the amount of rainwater that can enter the soil drastically reduces, leading to a further decrease in the availability of ground water.

Thus, we now understand that water enters the atmosphere as water vapor by the processes of evaporation and transpiration. Water vapor condenses to form clouds and

falls as rain. Rain water again runs off to large water bodies such as rivers, lakes, oceans, or groundwater.

Rajat wanted to observe the various processes that cause a change in the state of water in the environment. Let us try and mimic the processes.

Did you know that when rainwater flows on the ground, it washes away the valuable top soil? When this top soil is lost, plants cannot grow. This process is called soil erosion.

Water is found in many different states and these states keep changing depending on the temperature and other environmental conditions.

More to perform, observe, and learn

We can observe the processes that occur in the environment in our everyday lives. Do you notice that when water is placed in ice trays and kept in a freezer, it changes into solid ice cubes? Further, when water is heated in a pan, it changes into gaseous vapors. You may also have observed that on heating water in a container that is covered with a lid, the water vapour cools down after some time to form droplets of water under the lid! When a glass filled with icy cold water is kept on the table, in normal temperatures, small droplets of water are formed over the external surface of the glass.

Rainwater Harvesting

Water is a precious resource. However, as a result of over utilization and negligence on the part of humans, a considerable amount of it is wasted.

Wastage of water occurs at many places. Some instances include

- When the municipal water supply pipes leak or break, it results in a lot of water being wasted
- When we keep the taps running during shaving, bathing, washing, etc., we waste a lot of water
- Rain water, a valuable source of water flows into the drains, etc and gets wasted

In order to prevent this loss of water we need a proper system for the management of water.

Planned development, effective distribution and limiting the amount of water utilized for all activities are factors underlying the principle of water management.

Some of the methods which help in managing the water resources are discussed below

Rainwater harvesting

Collecting rainwater for use in future by storing it in storage reservoirs is called rainwater harvesting.

When rainwater falls on the ground, it runs down into the lakes, rivers, ponds, seas, and oceans. Some of it also evaporates into the air. Thus, precious rainwater is lost. To stop this loss of water, rainwater is collected and stored for future use. It is done by using different methods listed below.

Rooftop rainwater harvesting

In rooftop rainwater harvesting, the water storage tank is always installed below the ground level.

Rainwater storage as ground water

Another simple method of conservation of water is to allow the rainwater that falls on the ground to be absorbed into the soil so as to increase or add to the ground water content.

A 2400 sq feet area that receives an average rainfall of about 120 cm annually (a moderate rainfall area) can harvest about 22, 9000 litres of water. Therefore, if rainwater is conserved, then scarcity of water will definitely decrease.

In India rain water harvesting is an age old practice followed in many areas. Have you heard of *Bawris*? These are traditional architectural wonders that were built in the state of Rajasthan. They were used for collecting water. In course of time, these traditional structures became unused and waste materials started to deposit on these reservoirs.

Acute shortage of water in these areas forced the people to start thinking again about the traditional methods of water harvesting.

Many traditional and scientific agricultural techniques help to reduce the rate of water consumption. One such method in agriculture is **drip irrigation**.

Drip irrigation is a method of irrigation in which irrigation water is supplied to the plants directly using

small pipes, thereby reducing both the consumption and loss of water.

Effects of scarcity of water:

Health:

In many developing countries, people are forced to drink low quality water from flowing streams, many of which are contaminated. There are many water-borne diseases that leads to people die. Less water also means sewage does not flow, and mosquitoes are other insects breed on stagnant dirty water. This will result in infectious diseases like malaria.

Lack of quality water causes huge sanitation issues, i.e., In many place like clinics, restaurants, public places, people are forced to use very little water for cleaning. They indirectly compromises with the health of staff members and people who use the facilities.

Hunger:

It takes a lot of water to grow food and care for plants and animals. We use 70% of water sources for agriculture and irrigation and rest 30% for domestic purpose. Less water means lower yield. It means farm animals will die and others will not do well without water. The result is constant hunger, thirst and low quality of life.

Education:

It is a bit hard to see how water and education is related to each other. In many places,

Boys have to walk for several miles to get water. They get tired and some have to miss school. As a result, their education get hampered. In other places, girls and women are not allowed to go to school at all so that they can serve the family by getting water and taking care of other family needs.

Poverty:

Access of quality water is a key to economic prosperity and better living standards. Restaurants, hotels and shopping places need to keep clean to attract tourists and foreign investments. Manufacturing activities, commercial farms, and mining processes all need a lot of water to thrive. Lack of water means no economic activities will happen and the people will be in constant poverty.

Consequences of Excess And Scarce Rainfall

We have all experienced rainfall. Some of us might have also enjoyed playing in the rain.

Rainfall is important for life as

- It brings down the temperature in hot regions
- Increases the level of water in the water bodies
- Prepares the land for sowing in agricultural regions etc.

Rainfall is not constant across all regions. The duration, the season and the amount of rainfall varies from one region to another. Some regions receive rainfall throughout the year, while other regions do not receive sufficient rainfall even during the rainy seasons.

We see that during heavy rains the normal day-to-day life gets affected. You might have been disappointed when you had to miss your outdoor games during the rains. You might have also observed how the overflowing of rainwater leads to a blockage of traffic on the roads.

What would happen if there is an excess of rainfall in a certain region?

Some of the effects of heavy rainfall are

• In agricultural lands, it affects the crops as these get submerged under water

- It affects animals as they may get washed away with water. Sometimes, these animals may also get trapped on lands that are surrounded with water and may die.
- Increase in the level of water in ponds, lakes, and other water bodies may lead to overflowing of water. This may cause villages, towns and cities to submerge, thereby resulting in damages to both life and property.

A rise in the normal water levels in water bodies like lakes, rivers, ponds etc. in certain areas, as a result of heavy rainfall over a long period, causes a lot of damage to life and property. Such situations are called floods.

Now that you know what would happen during heavy rainfall, imagine what would happen if there was no rainfall

We often hear our parents telling us not to waste water. We see people storing water in pots, containers, tanks etc. We observe that plants die when there is insufficient water.

Let us list some of the consequences of a region receiving poor rainfall

- In agricultural lands, crop production would be adversely affected
- Water is important for animals therefore animal life would be affected
- There would be a decrease in the water levels in ponds, lakes, and other water bodies. This may lead to a shortage of water even for day-to-day activities.

The environmental condition where shortage of rainfall affects life is called a drought.
