

## HOTS (Higher Order Thinking Skills)

**Que 1.** A man standing on the deck of a ship, which is 10 m above the water level, observes the angle of elevation of the top of a hill as  $60^\circ$  and the angle of depression of the base of the hill as  $30^\circ$ . Calculate the distance of the hill from the ship and the height of the hill.

**Fig. 11.51**

**Sol.** In **Fig. 11.15**, let C represents the position of the man on the deck of the ship, A represents the top of hill and D its base.

Now in right-angled triangle CWD,

$$\tan 30^\circ = \frac{10}{WD} \quad \Rightarrow \quad WD = \frac{10}{\tan 30^\circ}$$

$$\Rightarrow \quad WD = \frac{10}{\frac{1}{\sqrt{3}}} = 10\sqrt{3} = 17.3 \text{ m}$$

Also, in right-angled triangle ABC, we have,

$$\tan 60^\circ = \frac{AB}{BC} \text{ or } \frac{AB}{WD} \quad [\text{From fig. } BC = WD]$$

$$\Rightarrow \quad \sqrt{3} = \frac{AB}{10\sqrt{3}} \quad \Rightarrow \quad AB = 10\sqrt{3} \times \sqrt{3} = 30 \text{ m}$$

Now,  $AD = AB + BD = 30 \text{ m} + 10 \text{ m} = 40 \text{ m}$ .

Therefore, the distance of the hill from the ship = 17.3 m and height of the hill = 40 m

**Que 2.** The angle of elevation of the top of a building from the foot of the tower is  $30^\circ$  and the angle of elevation of the top of the tower from the foot of the building is  $60^\circ$ . If the tower is 50 m high, find the height of the building.

**Fig. 11.52**

**Sol.** Let AB be the building of height  $h$  m and CD be the tower of height 50 m. We have,  
 $\angle ACB = 30^\circ$  and  $\angle DAC = 60^\circ$

Now, in  $\triangle ACD$ , we have

$$\tan 60^\circ = \frac{DC}{AC} \quad \Rightarrow \quad \sqrt{3} = \frac{50}{AC}$$

$$\Rightarrow AC = \frac{50}{\sqrt{3}} = \frac{50}{\sqrt{3}} \times \frac{\sqrt{3}}{\sqrt{3}} = \frac{50\sqrt{3}}{3}$$

$$\Rightarrow AC = \frac{50\sqrt{3}}{3} \quad \dots(i)$$

Now in  $\triangle ABC$ , we have

$$\tan 30^\circ = \frac{AB}{AC}$$

$$\Rightarrow \frac{1}{\sqrt{3}} = \frac{h}{AC} \quad \Rightarrow \quad AC = \sqrt{3}h$$

$$\therefore h = \frac{AC}{\sqrt{3}} = \frac{\frac{50\sqrt{3}}{3}}{\sqrt{3}} = \frac{50}{3} = 16\frac{2}{3} \text{ m} \quad (\text{From equation (i)})$$

Hence, the height of the building is  $16\frac{2}{3}$  m.

**Que 3.** From a window ( $h$  metres high above the ground) of a house in a street, the angles of elevation and depression of the top and the foot of another house on the opposite side of the street are  $\theta$  and  $\phi$  respectively. Show that the height of the opposite house is  $h(1 + \tan \theta \cot \phi)$ .

Fig. 11.53

**Sol.** Let W be the window and AB be the house on the opposite side.

Then, WP is the width of the street (**Fig. 11.53**).

Let AP =  $h'$  m

$$\text{In } \triangle BPW, \quad \tan \phi = \frac{PB}{WP}$$

$$\Rightarrow \quad \frac{h}{WP} = \tan \phi \quad \Rightarrow \quad WP = h \cot \phi \quad \dots(i)$$

$$\text{Now, in } \triangle AWP, \quad \tan \theta = \frac{AP}{WP} = \frac{h'}{WP}$$

$$\Rightarrow \quad h' = WP \tan \theta \quad \Rightarrow \quad h' = h \cot \phi \tan \theta$$

$$\therefore \quad \text{Height of house} = h' + h \\ = h \cot \phi \tan \theta + h (1 + \tan \theta \cot \phi)$$

**Que 4.** The angle of elevation of a jet plane from a point A on the ground is  $60^\circ$ . After a flight of 15 seconds, the angle of elevation changes to  $30^\circ$ . If the jet plane is flying at a constant height of  $1500\sqrt{3}$  m find the speed of the jet plane.

Fig. 11.54

**Sol.** Let P and Q be the two position of the plane and jet A be the point of observation. Let ABC be the horizontal line through A. It is given that angles of elevation of the plane in two positions P and Q from a point A are  $60^\circ$  and  $30^\circ$ , respectively.

Then,  $\angle PAB = 60^\circ, \angle QAB = 30^\circ$

It is also given that  $PB = 1500\sqrt{3}$  metres

In  $\triangle ABP$ , we have

$$\tan 60^\circ = \frac{BP}{AB} m$$

$$\Rightarrow \sqrt{3} = \frac{1500\sqrt{3}}{AB} \Rightarrow AB = 1500$$

In  $\triangle ACQ$ , we have

$$\tan 30^\circ = \frac{CQ}{AC} \Rightarrow \frac{1}{\sqrt{3}} = \frac{1500\sqrt{3}}{AC}$$

$$\Rightarrow AC = 1500 \times 3 = 4500 m$$

$$\therefore PQ = BC = AC - AB = 4500 - 1500 = 3000 m$$

Thus, the plane travels 3000 m in 15 seconds.

$$\text{Hence, the speed of plane} = \frac{3000}{15} = 200 = 200 m/s$$

$$= 200 \times \frac{3600}{1000} km/h = 200 \times \frac{18}{5} km/h = 720 km/h.$$

**Que 5.** If the angle of elevation of a cloud from a point  $h$  metres above a lake is  $\alpha$  and the angle of depression of its reflection in the lake is  $\beta$ , prove that the height of the cloud is  $\frac{h(\tan \beta + \tan \alpha)}{\tan \beta - \tan \alpha}$ .

**Sol.** Let  $AB$  be the surface of the lake and let  $P$  be a point of observation (**Fig. 11.55**) such that  $AP = h$  metres. Let  $C$  be the position of the cloud and  $C''$  be its reflection in the lake.

Then,  $CB = C''B$ . Let  $PM$  be perpendicular from  $P$  on  $CB$ . Then  $\angle CPM = \alpha$  and  $\angle MPC'' = \beta$ . Let  $CM = x$ .

Then,  $CB = CM + MB = CM + PA = x + h$ .

In  $\triangle CPM$ , we have

$$\tan \alpha = \frac{C''M}{PM} \Rightarrow \tan \alpha = \frac{x}{AB} \quad [\because PM = AB]$$

$$\Rightarrow AB = x \cot \alpha \quad \dots(i)$$

In  $\triangle PMC''$ , we have

$$\begin{aligned}\tan \beta &= \frac{C'M}{PM} \quad \Rightarrow \quad \tan \beta = \frac{x+2h}{AB} \quad [\because C'M = C'B + BM = x + h + h] \\ \Rightarrow \quad AB &= (x + 2h) \cot \beta \quad \dots(ii)\end{aligned}$$

From (i) and (ii), we have

$$\begin{aligned}x \cot \alpha &= (x + 2h) \cot \beta \quad \Rightarrow \quad x (\cot \alpha - \cot \beta) = 2h \cot \beta \\ \Rightarrow \quad x \left( \frac{1}{\tan \alpha} - \frac{1}{\tan \beta} \right) &= \frac{2h}{\tan \beta} \quad \Rightarrow \quad x \left( \frac{\tan \beta - \tan \alpha}{\tan \alpha \tan \beta} \right) = \frac{2h}{\tan \beta} \\ \Rightarrow \quad x &= \frac{2h \tan \alpha}{\tan \beta - \tan \alpha}\end{aligned}$$

Hence, the height CB of the cloud is given by

$$\begin{aligned}CB &= x + h \quad \Rightarrow \quad CB = \frac{2h \tan \alpha}{\tan \beta - \tan \alpha} + h \\ \Rightarrow \quad CB &= \frac{2h \tan \alpha + h \tan \beta - h \tan \alpha}{\tan \beta - \tan \alpha} = \frac{h (\tan \alpha + \tan \beta)}{\tan \beta - \tan \alpha}\end{aligned}$$
